Creates and returns a pointer to a database implementation.
- std::string [gldb::get_database_type](#) ()
Returns the name of the compiled-in database type.

6.2.1 Detailed Description

Module for interacting with the database.

6.2.2 Function Documentation

6.2.2.1 DBConnImp * glldb::get_connection (const std::string *database*, const std::string *hostname*, const std::string *username*, const std::string *password*)

Creates and returns a pointer to a database implementation.

The implementation of this function is provided by the individual database implementations. One database implementation is compiled into the program at any one time. Multiple database systems are, or will be, supported, and not every system will possess the libraries and headers to compile every implementation. Therefore, only one implementation is compiled in at a time. The fact that each database implementation will implement this function to return the correct derived class prevents any attempt to compile unsupported library code. This would not be feasible if we were to simply provide each implementation as a subclass.

Parameters

<i>database</i>	The name of the database to which to connect.
<i>hostname</i>	The hostname of the computer running the database.
<i>username</i>	The username with which to log into the database.
<i>password</i>	The password with which to log into the database.

Returns

A pointer to the database implementation.

6.2.2.2 std::string glldb::get_database_type ()

Returns the name of the compiled-in database type.

Returns

The name of the compiled-in database type.
